Version 1.2

Abstract

CLASS is a state-of-the-art **GILDAS**¹ software for reduction and analysis of (sub)–millimeter spectroscopic data. Up to now, the **CLASS** data format could only describe a predetermined number of parameters in the observation headers, these parameters being grouped in 17 *sections* (*e.g.* the general, spectroscopic or calibration sections). However, the possibility to add telescope-specific information to the **CLASS** data format was requested several time. Instead of introducing a per-telescope specific and fixed section, we thus decided to introduce a new flexible section, named *User Section*. This document describes the functionalities available to the end-users as well as the implementation steps which must be developed by the section owner.

Revisions:

- 1.0 (06-jul-2011): first release
- 1.1 (15-may-2013): added hook to command **FIND**
- 1.2 (27-apr-2015): added support for 2D arrays

1 Basic description and functionalities

A user section is now part of the **CLASS** data format. It can be added to the observations by any external program which is linked with the **CLASS** library and which uses the **CLASS** API.

The user section is composed of a basic owner and data descriptor, and of a data block. The content and length of the data is controlled by the section owner, but for a few restrictions described in this document. The data block is untyped, which means that the standard **CLASS** program is not able to understand it natively. Only its owner is able to do so with the appropriate decoding routines. On the other hand, the standard **CLASS** program is able to detect, load and propagate the User Section when possible. **CLASS** can also find all the observations containing a user section. However, users and programmers should be aware that there are **CLASS** operations under which the user section loses its meaning (for example **AVERAGE**'ing). These operations thus do not propagate the user function.

More precisely, the User Section can store several user *subsections*. Each of these is identified by a unique *owner* and *title* pair of values. The **CLASS** library will properly read and write in the correct subsection as long as the program has declared properly which one it owns. Each subsection has its own version number to enable the evolution of the data format (Note that abuse of the versioning mechanism may slow down operations on this section).

We also provide code hooks which enable external programs to work on the user sections when a few usual **CLASS** commands are called. These commands are **WRITE**, **GET**, **DUMP**, **SET VARIABLE USER**, **FIND**.

2 Adding a user subsection to an observation

In order to add a new user subsection to an observation, the external program has first to define a Fortran derived type containing the data. Scalar, 1D, or 2D-array values of types **INTEGER(4)**, **REAL(4)** and **REAL(8)** are supported. Scalar **CHARACTER(LEN=*)** strings are also supported, but their length must be a multiple of 4. The component names, their number, and their order is defined by the programmer. The derived type used by the external program does not need to have a Fortran **sequence** statement: the way its elements are ordered in memory is also free.

The external program can add its user section to an observation in 3 steps:

1. tell **CLASS** which subsection it owns thanks to the subroutine `class_user_owner`,
2. declare with `class_user_toclass` the subroutine which knows how to order and transfer to **CLASS** the user data,
3. finally send the data to **CLASS** with the subroutine `class_user_add` (for a new user subsection) or `class_user_update` (if the subsection already exists).

The 2 first steps can be done only once, while the last has to be repeated each time a new user section has to be added. The transfer subroutine declared at step 2 is mandatory to indicate to **CLASS** which elements are present in the data and in which order they have to be written.

2.1 Example

The following program adds a new User Section to a **CLASS** observation. A more realistic program would open an output file and write the observation into it. The data here contains dummy values and names for the example.

```
module mytypes
  type :: owner_title_version
    integer(kind=4)  :: datai4
    real(kind=4)     :: datar4
  end type
```

```

    real(kind=8)      :: datar8
    character(len=4)  :: datac4
end type owner_title_version
end module mytypes

program myprog
  use class_types
  use class_api
  use mytypes
  external :: toclass
  type(observation) :: obs
  type(owner_title_version) :: mydata
  integer(kind=4) :: version
  logical :: error
  !
  ! 1) Fill the data
  mydata%datai4 = 111
  mydata%datar4 = 222.
  mydata%datar8 = 333.
  mydata%datac4 = 'ABCD'
  !
  ! 2) Tell Class who I am
  call class_user_owner('OWNER','TITLE')
  !
  ! 3) Declare my transfer subroutine
  call class_user_toclass(toclass)
  !
  ! 4) Fill the User Section in the observation
  version = 1
  error = .false.
  call class_user_add(obs,version,mydata,error)
  if (error) stop
  !
end program myprog

subroutine toclass(mydata,version,error)
  use class_api
  use mytypes
  !-----
  ! Transfer and order the input 'mydata' object to the internal Class
  ! data buffer.
  !-----
  type(owner_title_version), intent(in)    :: mydata    !
  integer(kind=4),           intent(in)    :: version   ! The version of the data
  logical,                   intent(inout) :: error      ! Logical error flag
  !
  if (version.ne.1) then
    print *, 'TOCLASS: Unsupported data version ', version
    error = .true.
    return
  endif
  !
  call class_user_datatoclass(mydata%datai4)

```

```

call class_user_datatoclass(mydata%datar4)
call class_user_datatoclass(mydata%datar8)
call class_user_datatoclass(mydata%datac4)
!
end subroutine toclass

```

2.2 Detailed API

The following subroutines are part of the Class User Section API. The interface module named `class_user_interfaces` MUST be used in the calling program or subroutines:

- Declare the owner and title of the User Subsection:

```

subroutine class_user_owner(sowner,stitle)
  character(len=*), intent(in) :: soowner ! Section owner
  character(len=*), intent(in) :: stitle ! Section title

```

- Declare the user's transfer routine

```

subroutine class_user_toclass(usertoclass)
  external :: usertoclass ! User's 'toclass' subroutine

```

- Send a variable to the data buffer in **CLASS**:

```

subroutine class_user_datatoclass(var)
  integer(kind=4), intent(in) :: var
OR  real(kind=4), intent(in) :: var
OR  real(kind=8), intent(in) :: var
OR  character(len=*), intent(in) :: var

```

- Add the User Subsection to an observation:

```

subroutine class_user_add(obs,sversion,sdata,error)
  type(observation), intent(inout) :: obs ! Observation
  integer(kind=4), intent(in) :: sversion ! Version number
  type( ), intent(in) :: sdata ! The user data
  logical, intent(inout) :: error ! Logical error flag

```

- Update the User Subsection in the input observation:

```

subroutine class_user_update(obs,sversion,sdata,error)
  type(observation), intent(inout) :: obs ! Observation
  integer(kind=4), intent(in) :: sversion ! Version number
  type( ), intent(in) :: sdata ! The user data
  logical, intent(inout) :: error ! Logical error flag

```

Finally, the calling sequence of the user's transfer routine must be of the following form:

```

subroutine toclass(data,version,error)
  type( ), intent(in) :: data ! The data to be transfered to Class
  integer(kind=4), intent(in) :: version ! The version of the data
  logical, intent(inout) :: error ! Logical error flag

```

The name of this subroutine is to be defined by the user. The data *type* can be of any kind provided by the user. The purpose of this routine is to send the **data** elements to **CLASS** in a given order. The advantage of this mechanism is to leave **CLASS** compute the whole **data** size and store it as its will. The counterpart is that the order must be then exactly respected in the other parts of the user code, *e.g.* in the reading subroutine **fromclass** defined hereafter. Furthermore, the **CLASS** API does not allow to read only one element in the **data**.

3 Reading a user section from an observation

When the observation which is read from a file contains a user section, **CLASS** will load it entirely (i.e. all the subsections it may contain). The **data** block of each subsection is loaded “as is” in memory. Nothing more is done at read time.

4 Adding hooks to the Class commands

The key point is now: “*How users can access the user subsection in the context of CLASS commands?*”. Let’s take the command **DUMP** as first example.

4.1 User hook for command DUMP

The command **DUMP** displays the content of one or all sections of the R buffer. When **CLASS** finds a user section to dump, it can display the information it knows about each subsection. What it can not do is guessing what the **data** block contains.

If the section owner wants to tell **CLASS** how to **dump** its subsection, it has to:

1. tell **CLASS** which subsection it owns with **class_user_owner**. This is optional if it has been done elsewhere.
2. declare to **CLASS** with **class_user_dump** a subroutine which is able to display what is in the **data** block.

If **CLASS** tries now to **DUMP** the user section, it will loop over all the subsections it contains. If one matches the owner+title couple, it will put the **data** block in a specific place, and then call user’s dump subroutine. This subroutine will then just have to translate back the **data** block to its own data type.

This last point must be fulfilled by a subroutine exactly symmetric to the transfer routine used at write time, i.e. elements should be reread in the same order they have been written.

4.1.1 Example

If no user hooks have been declared, the output of the command **DUMP /SECTION USER** will be (with the example shown in the previous section):

```
USER -----
Number of subsections: 1
User Section #    1
  Owner:          OWNER
  Title:           TITLE
  Version:         1
  Data length:    5
  Data:
    (can not dump)
```

CLASS claims it is not able to understand the content of the **data** buffer in the User Subsection.

The following subroutines show basically what should be done by the section owner to allow **CLASS** to **DUMP** a specific user section:

```

subroutine mydump_init
  !-----
  ! Preliminary declarations
  !-----
  !
  ! 1) Tell Class who I am
  call class_user_owner('OWNER','TITLE')
  !
  ! 2) Declare my dumping routine
  call class_user_dump(mydump)
  !
  ! Nothing more: return and wait for Class to ask for my User
  ! Subsection dump.
  !
end subroutine mydump_init

subroutine mydump(version,error)
  use mytypes
  !-----
  ! Dump to screen my User Subsection
  !-----
  integer(kind=4), intent(in)    :: version ! The version of the data
  logical,          intent(inout) :: error  ! Logical error flag
  ! Local
  type(owner_title_version) :: mydata
  !
  call fromclass(mydata,version,error) ! Read the Class buffer and fill mydata
  if (error) return
  !
  ! Display to screen
  print *, "    datai4 = ",mydata%datai4
  print *, "    datar4 = ",mydata%datar4
  print *, "    datar8 = ",mydata%datar8
  print *, "    datac4 = ",mydata%datac4
  !
end subroutine mydump

subroutine fromclass(mydata,version,error)
  use mytypes
  use class_api
  !-----
  ! Transfer the data values from the Class data buffer to the 'mydata'
  ! instance.
  !-----
  type(owner_title_version), intent(out) :: mydata !
  integer(kind=4),          intent(in)    :: version ! The version of the data
  logical,                  intent(inout) :: error  ! Logical error flag
  !

```

```

if (version.ne.1) then
  print *, 'FROMCLASS: Unsupported data version ', version
  error = .true.
  return
endif
!
call class_user_classtodata(mydata%datai4)
call class_user_classtodata(mydata%datar4)
call class_user_classtodata(mydata%datar8)
call class_user_classtodata(mydata%datac4)
!
end subroutine fromclass

```

With these subroutines, **CLASS** is now able to ask for a translation of the User Subsection. The output of the command `DUMP /SECTION USER` will be:

```

USER -----
Number of subsections: 1
User Section #      1
  Owner:           OWNER
  Title:           TITLE
  Version:         1
  Data length:     5
  Data:
    datai4 =          111
    datar4 =    222.00000
    datar8 =  333.000000000000000
    datac4 = ABCD

```

4.1.2 API

The following subroutines have to be used to declare user's dump subroutine:

- Declare the user's dump routine:

```

subroutine class_user_dump(userdump)
  external :: userdump ! User's 'dump' subroutine

```

- Get a variable from the data buffer in **CLASS**:

```

subroutine class_user_classtodata(var)
  integer(kind=4), intent(out) :: var
  OR real(kind=4),   intent(out) :: var
  OR real(kind=8),   intent(out) :: var
  OR character(len=*), intent(out) :: var

```

The calling sequence of the user's dump routine must be of the following form:

```

subroutine mydump(version,error)
  integer(kind=4), intent(in)   :: version ! The version of the data
  logical,          intent(inout) :: error  ! Logical error flag

```

The name of this subroutine is free.

4.2 User hook for command SET VARIABLE USER

If **CLASS** knows about a User Subsection owner and title when **SET VARIABLE USER** is invoked, it can instantiate the SIC variables which describe the data of this subsection. This is be done if the associated hook has been defined and declared to **CLASS**. The steps to do so are, as usual:

1. tell **CLASS** which subsection it owns with `class_user_owner`. This is optional if it has been done elsewhere.
2. declare to **CLASS** with `class_user_setvar` a subroutine which is able to instantiate the SIC variables associated to the User Subsection.

The subroutines `class_user_def_inte`, `class_user_def_real` and `class_user_def_dble` and `class_user_def_char` will create respectively an integer*4, real*4 and real*8 and character string in `R%USER%OWNER%` (where `OWNER` is the owner previously declared). The subroutines order must match the order the data was written in the User Section buffer.

The calling sequence of these subroutines is described in the following sections. The suffix name of the SIC variable is given as first argument, e.g. `FOO` for `R%USER%OWNER%FOO`. The arguments 'ndim' and 'dims' describe the variable dimensions, but only scalars, 1D, and 2D-arrays are currently supported (ndim=0, 1, or 2). For the character variables, 'strlen' is the string length which has to be read from the buffer.

Note that once it has been instantiated, the SIC structure `R%USER%OWNER%` will be updated each time the data changes (e.g. after a `GET NEXT`).

4.2.1 Example

When **CLASS** does not know about the User Subsection, it will not accept to instantiate the SIC structure `R%USER%`:

```
LAS90> set variable user
E-SETVAR, No user function set for SET VAR USER
LAS90> exa r%user%
E-EXAMINE, No such variable R%USER
```

The following subroutines show basically what should be done by the section owner to allow **CLASS** to instantiate SIC variables pointing to the User Subsection when the command **SET VARIABLE USER** is invoked.

```
subroutine mysetvar_init
!-----
! Preliminary declarations
!-----
!
! 1) Tell Class who I am
call class_user_owner('OWNER','TITLE')
!
! 2) Declare my instantiation routine
call class_user_setvar(mysetvar)
!
! Nothing more: return and wait for Class to ask for my User
! Subsection instantiation.
!
end subroutine mysetvar_init

subroutine mysetvar(version,error)
use mytypes
```

```

!-----
! Define SIC variables in the structure R%USER%OWNER% which map the
! subsection content.
!-----
integer(kind=4), intent(in)    :: version ! The version of the data
logical,          intent(inout) :: error   ! Logical error flag
! Local
logical :: error
integer(kind=4) :: ndim,dims
!
error = .false.
ndim = 0
call class_user_def_inte('DATAI4',ndim,dims,error)
call class_user_def_real('DATAR4',ndim,dims,error)
call class_user_def_dble('DATAR8',ndim,dims,error)
call class_user_def_strn('DATAAC4',ndim,dims,error)
if (error) return
!
end subroutine mysetvar

```

With these routines, **CLASS** is now able to instantiate the SIC variables:

```

MYPROG> set variable user
MYPROG> exa r%user%
R%USER%          ! Structure GLOBAL
R%USER%OWNER%DATAAC4 = ABCD                ! Character*4 GLOBAL RO
R%USER%OWNER%DATAR8 = 333.00000000000000    ! Double GLOBAL RO
R%USER%OWNER%DATAR4 = 222.0000              ! Real GLOBAL RO
R%USER%OWNER%DATAI4 = 111                   ! Integer GLOBAL RO
R%USER%OWNER      ! Structure GLOBAL

```

4.2.2 API

The following subroutines have to be used in order to instantiate SIC variables in the structure R%USER%.

- Declare the user's subroutine for variables instantiation:

```

subroutine class_user_setvar(usersetvar)
  external :: usersetvar

```

- Instantiate a SIC variable in R%USER%OWNER% (numeric types, respectively integer*4, real*4 and real*8). Only scalars (ndim=0), 1D (ndim=1), and 2D-arrays (ndim=2) are currently supported.

```

subroutine class_user_def_inte(suffix,ndim,dims,error)
  character(len=*), intent(in)    :: suffix    ! Component name
  integer(kind=4),  intent(in)    :: ndim      ! Number of dimensions (0=scalar)
  integer(kind=4),  intent(in)    :: dims(4)   ! Dimensions (unused if scalar)
  logical,          intent(inout) :: error     ! Logical error flag

subroutine class_user_def_real(suffix,ndim,dims,error)
  character(len=*), intent(in)    :: suffix    ! Component name
  integer(kind=4),  intent(in)    :: ndim      ! Number of dimensions (0=scalar)
  integer(kind=4),  intent(in)    :: dims(4)   ! Dimensions (unused if scalar)
  logical,          intent(inout) :: error     ! Logical error flag

```

```

subroutine class_user_def_dble(suffix,ndim,dims,error)
  character(len=*), intent(in)    :: suffix    ! Component name
  integer(kind=4),  intent(in)    :: ndim      ! Number of dimensions (0=scalar)
  integer(kind=4),  intent(in)    :: dims(4)   ! Dimensions (unused if scalar)
  logical,          intent(inout) :: error     ! Logical error flag

```

- Instantiate a SIC variable in R%USER%OWNER% (scalar character strings).

```

subroutine class_user_def_char(suffix,lstring,error)
  character(len=*), intent(in)    :: suffix    ! Component name
  integer(kind=4),  intent(in)    :: lstring   ! String length
  logical,          intent(inout) :: error     ! Logical error flag

```

The calling sequence of the user's instantiation routine must be of the following form:

```

subroutine mysetvar(version,error)
  integer(kind=4), intent(in)    :: version   ! The version of the data
  logical,          intent(inout) :: error     ! Logical error flag

```

The name of this subroutine is free.

4.3 User hook for command FIND

The **CLASS** command **FIND** allows the user to make a custom selection from the Input indeX (IX: input file summary), building then the Current indeX (CX). This is done through the option **/USER**. If **CLASS** knows about a User Subsection owner and title, then a hook can be executed in order to make a custom search depending on this User Subsection contents. The basic steps to be done by the Subsection owner are:

1. tell **CLASS** which subsection it owns with **class_user_owner**. This is optional if it has been done elsewhere.
2. declare to **CLASS** with **class_user_find** a subroutine which will parse the **FIND /USER** arguments,
3. declare to **CLASS** with **class_user_fix** a subroutine which will make the selection depending on the command line arguments and the Subsection contents.

4.3.1 Example

When **CLASS** does not know about the User Subsection, it will not accept to make a custom user selection:

```

LAS90> FIND /USER
E-USER_SEC_FIND, No user function for FIND /USER

```

The following subroutines show basically what should be done by the section owner to allow **CLASS** such custom selections. Note that this is divided into 2 main steps. The command line parsing is first called. For efficiency, this is done only once at the beginning of the command execution. Then **CLASS** loops on all the observations in the Input indeX and calls repeatedly the selection subroutine.

```

subroutine myfind_init
!-----
! Preliminary declarations
!-----
!
! 1) Tell Class who I am

```

```

call class_user_owner('OWNER','TITLE')
!
! 2) Declare my command line parsing subroutine
call class_user_find(myfind)
!
! 3) Declare my selection subroutine
call class_user_fix(myfix)
!
! Nothing more: return and wait for Class to execute FIND /USER.
!
end subroutine myfind_init

subroutine myfind(arg,narg,error)
  use gkernel_interfaces
  use mymod
  !-----
  ! Hook to command:
  !   LAS\FIND /USER [Arg1] ... [ArgN]
  ! Command line parsing: retrieve the arguments given to the option.
  !-----
  integer(kind=4), intent(in)    :: narg      ! Number of arguments
  character(len=*), intent(in)   :: arg(narg) ! Arguments
  logical,          intent(inout) :: error    ! Logical error flag
  ! Local
  integer(kind=4) :: iarg
  !
  ! Here you have to parse and save the selection criteria given to
  ! the command line. We assume here they are saved in a float array
  ! 'mycriteria' provided by the module 'mymod'
  mycriteria(:) = 0.0 ! Initialization
  !
  do iarg=1,narg
    ! Use Gildas kernel parsing subroutines (convert string to REAL*4)
    call sic_math_real(arg(iarg),len(arg(iarg)),mycriteria(iarg),error)
    if (error) return
  enddo
  !
end subroutine myfind

subroutine myfix(version,found,error)
  use mymod
  use mytypes
  !-----
  ! Hook to command:
  !   LAS\FIND /USER
  ! Find or not according the User Subsection contents. Called only if
  ! the observation has a user section and it matches the one
  ! declared here.
  ! NB: 'FIX' stands for "Find in Input indeX"
  !-----
  integer(kind=4), intent(in)    :: version ! The version of the data
  logical,          intent(out)  :: found   ! Selected or not selected?
  logical,          intent(inout) :: error   ! Logical error flag

```

```

! Local
type(owner_title_version) :: mydata
!
call fromclass(mydata,version,error) ! Read the Class buffer and fill mydata
if (error) return
!
! Use the criteria saved in 'myfind' e.g.
found = mydata%r4.gt.mycriteria(1) .and. mydata%r8.lt.mycriteria(2)
!
end subroutine myfix

```

With these routines, **CLASS** is now able make a custom search in the input index:

```

MYPROG> find ! Find everything
I-FIND, 15504 observations found
MYPROG> find /user 1.0 2.0 ! Find with some user selection
I-FIND, 224 observations found

```

The option /USER can be combined with other selection criteria (e.g. FIND /SOURCE MYSOURCE /USER 1.0); as usual the result is the intersection of all the selections. If FIND /USER is invoked but the User Subsection is absent or is not owned by the program, the observation is not selected to the Current index².

4.3.2 API

The following subroutines have to be used to declare user's find subroutine:

- Declare the user's dump find routines:

```

subroutine class_user_find(userfind)
  external :: userfind ! User's 'find' subroutine (command line parsing)
subroutine class_user_fix(userfix)
  external :: userfix ! User's 'find' subroutine (selection)

```

The calling sequence of the user's find routines must be of the following form:

```

subroutine userfind(arg,narg,error)
  integer(kind=4), intent(in) :: narg ! Number of arguments
  character(len=*), intent(in) :: arg(narg) ! Arguments
  logical, intent(inout) :: error ! Logical error flag

subroutine userfix(version,found,error)
  integer(kind=4), intent(in) :: version ! The version of the data
  logical, intent(out) :: found ! Selected or not selected?
  logical, intent(inout) :: error ! Logical error flag

```

The name of these subroutines is free.

4.4 API summary

The table 1 describes the general hooks to be used in order to read or write the User Section. They have to be considered as prerequisites before doing anything with this section in **CLASS**.

The table 2 describe the hooks to be used when adding a User Section to an observation (e.g. before writing it to the output file).

Finally the table 3 summarizes the subroutines which can be used to declare the hooks to some **CLASS** commands, plus some subroutines which are useful for some of them.

²Remember that Class provides natively the option FIND /SECTION USER which finds all observations providing a User Section, independently from any hook.

Table 1: General hooks

Subroutine	Purpose
<code>class_user_owner</code>	declare who is the owner and what is the title of the subsection the hooks can read or write

Table 2: Writing hooks

Subroutine	Purpose
<code>class_user_add</code>	add a new user subsection to the input observation
<code>class_user_update</code>	update a user subsection which already exists
<code>class_user_toclass</code>	declare the subroutine which will write the data to the Class internal buffer
<code>class_user_datatoclass</code>	transfer a scalar, 1D, or 2D-array value to the Class internal buffer (generic subroutine)

Table 3: Reading hooks

Subroutine	Purpose
<code>class_user_dump</code>	declare the hook for the command <code>DUMP</code>
<code>class_user_find</code>	declare the hook for the command <code>FIND /USER</code> (command line parsing)
<code>class_user_fix</code>	declare the hook for the command <code>FIND /USER</code> (selection)
<code>class_user_setvar</code>	declare the hook for the command <code>SET VARIABLE USER</code>
<code>class_user_classtodata</code>	read a scalar, 1D, or 2D-array value from the Class internal buffer (generic subroutine)
<code>class_user_def_inte</code>	create an integer*4 SIC variable in the structure <code>R%USER%OWNER%</code>
<code>class_user_def_real</code>	create a real*4 SIC variable in the structure <code>R%USER%OWNER%</code>
<code>class_user_def_dble</code>	create a real*8 SIC variable in the structure <code>R%USER%OWNER%</code>
<code>class_user_def_char</code>	create a character string SIC variable in the structure <code>R%USER%OWNER%</code>

5 Extending the standard CLASS capabilities

The previous sections describe how to write and read a User Section in/from a **CLASS** file. This was assumed to be done from an external program linked to be **CLASS** library. However, it is also possible to do this directly from the standard **CLASS** executable. The key point is to define all the support subroutines for the User Section in a binary, dynamically loadable library (say *libowner.so*), linked to the **CLASS** library. *libowner.so* must also define a specific entry point and its associated definition subroutines, as described in the document named *New package initialization*³.

From a standard **CLASS** session, the command `SIC\IMPORT` can then be used to load the *libowner.so* library and import the User Section capabilities. Such a session will look like:

```
LAS90> ! First, Class does not know how to read the User Section:
```

```
LAS90> DUMP /SECTION USER
```

```
USER -----
Number of subsections: 1
User Section #      1
  Owner:            OWNER
  Title:            TITLE
  Version:          1
  Data length:      5
  Data:
    (can not dump)
```

```
LAS90>
```

```
LAS90> ! Load 'libowner.so'
```

```
LAS90> SIC\IMPORT OWNER
```

```
LAS90>
```

```
LAS90> ! Now Class knows how to read it:
```

```
LAS90> DUMP /SECTION USER
```

```
USER -----
Number of subsections: 1
User Section #      1
  Owner:            OWNER
  Title:            TITLE
  Version:          1
  Data length:      5
  Data:
    datai4 =          111
    datar4 =      222.00000
    datar8 = 333.000000000000000
    datac4 = ABCD
```

```
LAS90>
```

6 Backward compatibility

Old versions of **CLASS** (i.e. older than apr11g) will just ignore the user section, if it exists. This section will be lost in a GET-and-WRITE process.

Starting from apr11g, **CLASS** is able to detect, load and give basic details about this section. All the user subsections are preserved and written to the output file, under the restrictions exposed in the next section.

³contact gildas@iram.fr for more information

7 Portability

The basic behavior of **CLASS** is that it loads all the user subsections (if any) at read time, and transfer all of them to the output file at write time. However, the **data** block of bytes is untyped in the **CLASS** data format, so it will make sense to re-read them if and only if the reading machine has the same endianness (IEEE, EEI, etc) than the one used at write time. As a consequence the following restrictions apply:

1. at read time, **CLASS** won't read the user section if the input file type is not native (i.e. it has not been written under the same architecture we are reading it),
2. at write time, **CLASS** won't write the user section if the output file type is not native (i.e. we reopened for output a file first written under another architecture).

However, these restrictions have very low chance to occur, since nowadays most (all?) of the computers have an IEEE architecture.

8 Conclusion

The **CLASS** developer team provides some flexibility about the **CLASS** data format through a customizable user section mechanism. This user section can be encoded and decoded only by external programs linked with the **CLASS** library and which follows the **CLASS** API. This is the responsibility of the external programs to ensure the efficiency of their codes. We recommend to observatory who would like to use this mechanism to contact us (gildas@iram.fr) in order to discuss how to maintain the long term compatibility of their user section.

A Implementation details for CLASS developers

The User Section is added to the **CLASS** data format. It is defined in the Fortran source as follows:

```
type user ! Type for all user subsections
  sequence
  integer(kind=4)      :: n      ! Number of user subsections
  type (user_sub), pointer :: sub(:) ! Array of subsections
end type
```

An object of type **user** is added to the type **observation** structure in the data format. This **user** object can contain an arbitrary number of subsections. This allows several user subsections to exist for the same observation.

Then each of these user subsection is described by the following type:

```
type user_sub ! Type for each user subsection
  sequence
  character(len=12)      :: owner    ! Owner of the subsection
  character(len=12)      :: title    ! Title of the subsection
  integer(kind=4)        :: version  ! Version of the subsection
  integer(kind=4)        :: ndata    ! Length of the data(:) array
  integer(kind=4), pointer :: data(:) ! Place holder for information
end type
```

- A user subsection is identified by a **owner** and a **title**. One owner can have several subsections with each a different title. In other words the couple **owner+title** is considered as a unique identifier for a user subsection.
- The **version** value is a mean for the owner to handle several versions of the same subsection (e.g. elements have been added in this subsection between two versions).
- The **data** field is the data itself. It is considered as a block of bytes with no direct meaning for **CLASS**. Only the owner is able to decode it.
- Since the **data** is a dynamic object (i.e. size is not known at compilation time), the **ndata** value describes how many 4-bytes blocks are present in the **data**.

Those two types are private to **CLASS**. They do not have to be known by the external program.

Finally, this new User Section is different from the other ones in the **CLASS** data format since its size is not constant. This implies some modifications in the subroutines. In particular, a whole copy of observation to observation (**obsout** = **obsin**) is forbidden: it must be done in a specific way, taking care of allocating the pointers in the user section before the copy. For the same reason, the User Section is not buffered and must be re-read everytime needed on the disk (in other words **SET VIRTUAL ON** has no effect).
